

# WEB PAGES DESIGN

## Java Script

Lecturer: M.Sc. Ahmed Sami

Lecture 10.

Class 2.

Department: Informatics Systems Management (ISM)

# Java Script overview

## What is JavaScript?

- **JavaScript** is the scripting language of the Web.
- **JavaScript** is used in millions of Web pages to improve the design, validate forms, detect browsers, create cookies, and much more.
- **JavaScript** is a dynamic computer programming language. It is lightweight and most commonly used as a part of web pages, whose implementations allow client-side script to interact with the user and make dynamic pages.

# Java Script overview

- Scripts can be executed on client or the server.

Client Side Scripting	Server Side Scripting
Runs on the user's computer i.e. Browser interprets the script	Runs on the Web server
Visible to users if they view the HTML source	Not visible to user

- **JavaScript** is mainly used as a client side scripting language.
- **JavaScript** was initially called as Live Script.
- **JavaScript** is a lightweight, interpreted programming language.
- **JavaScript** is used to implement programming on client-side web documents.
- **JavaScript** is used for file handling and database connectivity on the server-side.
- **JavaScript** is used for validating user input on client-side.

# Java Script

Java script is object based oriented language:

- Inheritance is does not support in JavaScript, so it is called object based oriented language.

Java script is also called light weight programming language:

- because Java script is return with very simple syntax. Java script is containing executable code.

Java script is also called interpreted language:

- because script code can be executed without preliminary compilation.

# why we use Java Script

## Why we Use JavaScript?

- Using HTML we can only design a web page but you can not run any logic on web browser like addition of two numbers, check any condition, looping statements (for, while), decision making statement (if-else) at client side. All these are not possible using HTML So for perform all these task at client side you need to use JavaScript.

# Java Script vs. Java

## JavaScript

- Interpreted
- Mainly used for front-end
- client side language
- Needs more effort to enhance security
- The syntax is similar to python and C.
- Can be written in any text editor
- Mainly for web apps

## Java

- Compiled
- Mainly used for back-end
- Server side language
- Allows better security
- The syntax is similar to C++ and C#.
- Requires Java Development Kit (JDK)
- Mainly for various apps

# Compiled vs. Interpreted

## Compiled

- is converted into machine code so that the processor can execute it.
- The compiled programs run faster than interpreted programs.
- This language delivers better performance.

## Interpreted

- is a language in which the implementations execute instructions directly without earlier compiling a program into machine language.
- The interpreted programs run slower than the compiled program.
- This language delivers slower performance.

# features of Java Script

## Features of JavaScript:

- JavaScript is a client side technology, it is mainly used for gives client side validation, but it have lot of features which are given below.

# Creating a Java Script

## Creating a java script:

- html script tag is used to script code inside the html page.

`<script> ..... </script>`

The script is containing 2 attributes. They are:

### 1- Language attribute:

It represents name of scripting language such as JavaScript, VbScript.

`<script language="JavaScript">`

### 2- Type attribute:

It indicates MIME (multi purpose internet mail extension) type of scripting code. It sets to an alpha-numeric MIME type of code.

`<script type="text / JavaScript">`

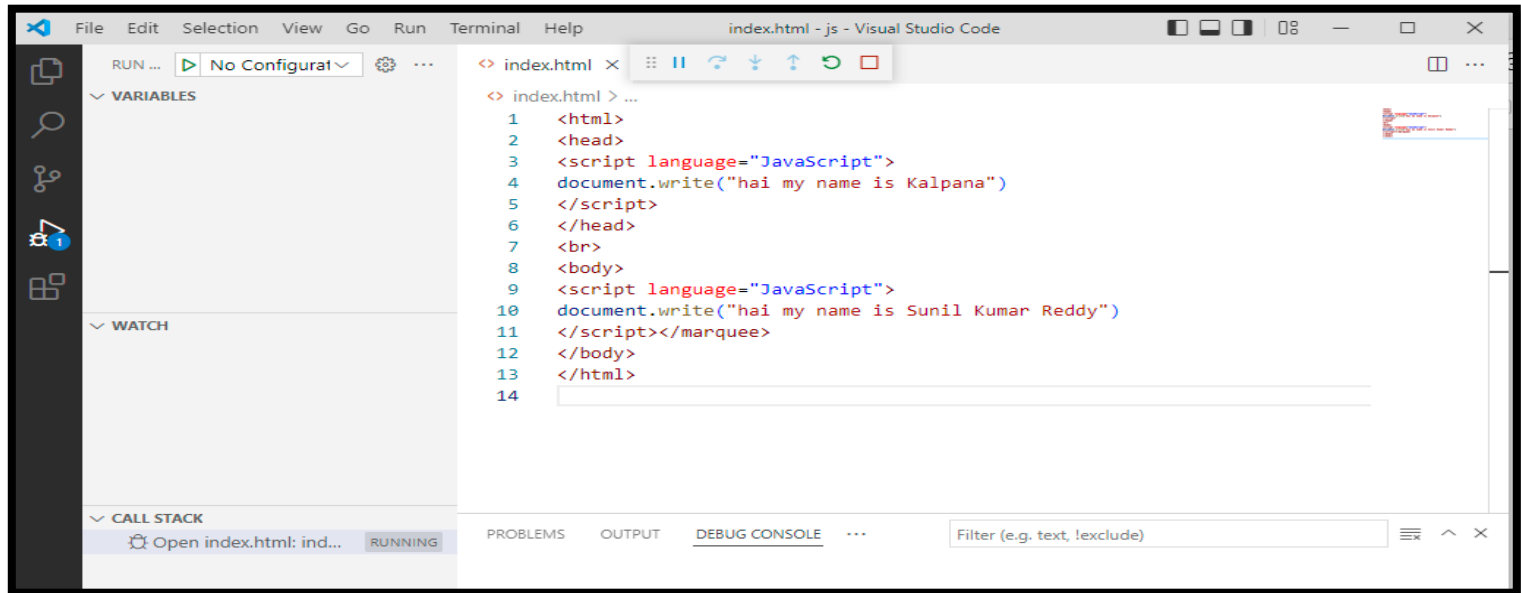

# Creating a Java Script

## Scripting in both head & body section:

- we can create unlimited number of scripts inside the same page. So we can locate multiple scripts in both head & body section of page.

```
Ex: - <html>
      <head>
      <script type="text / JavaScript">
          Script code here
      </script>
      </head>
      <body>
      <script type="text / JavaScript">
          Script code here
      </script>
      </body>
      </html>
```

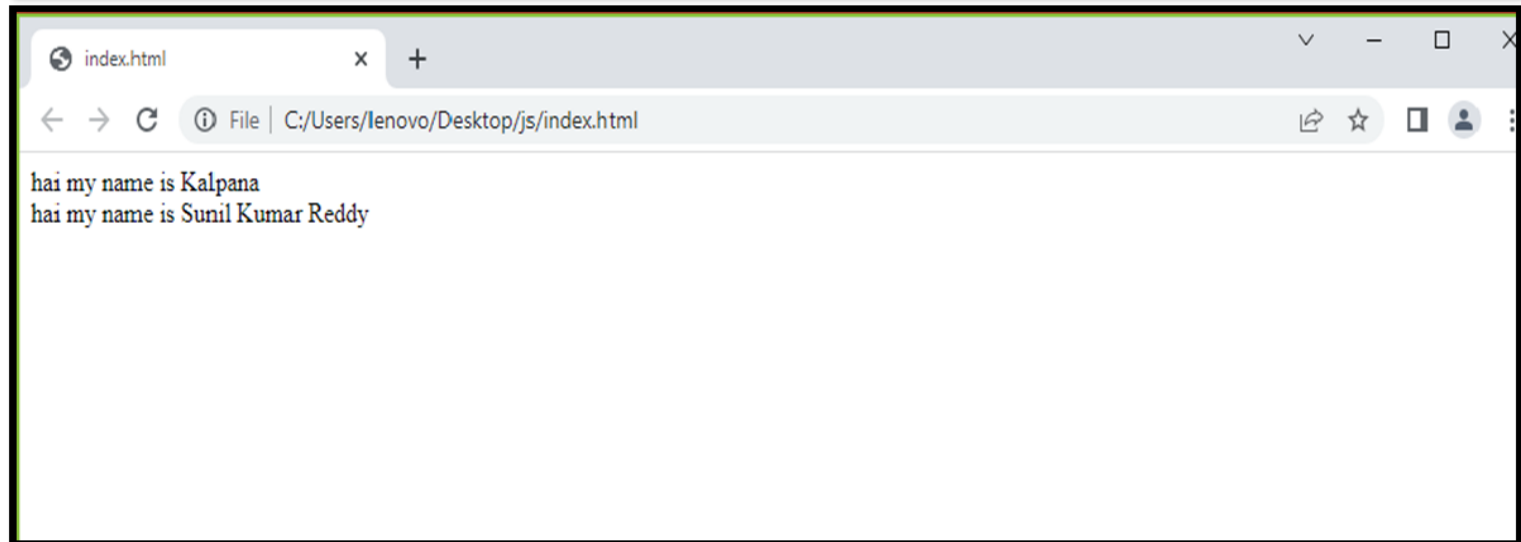

# Example 1

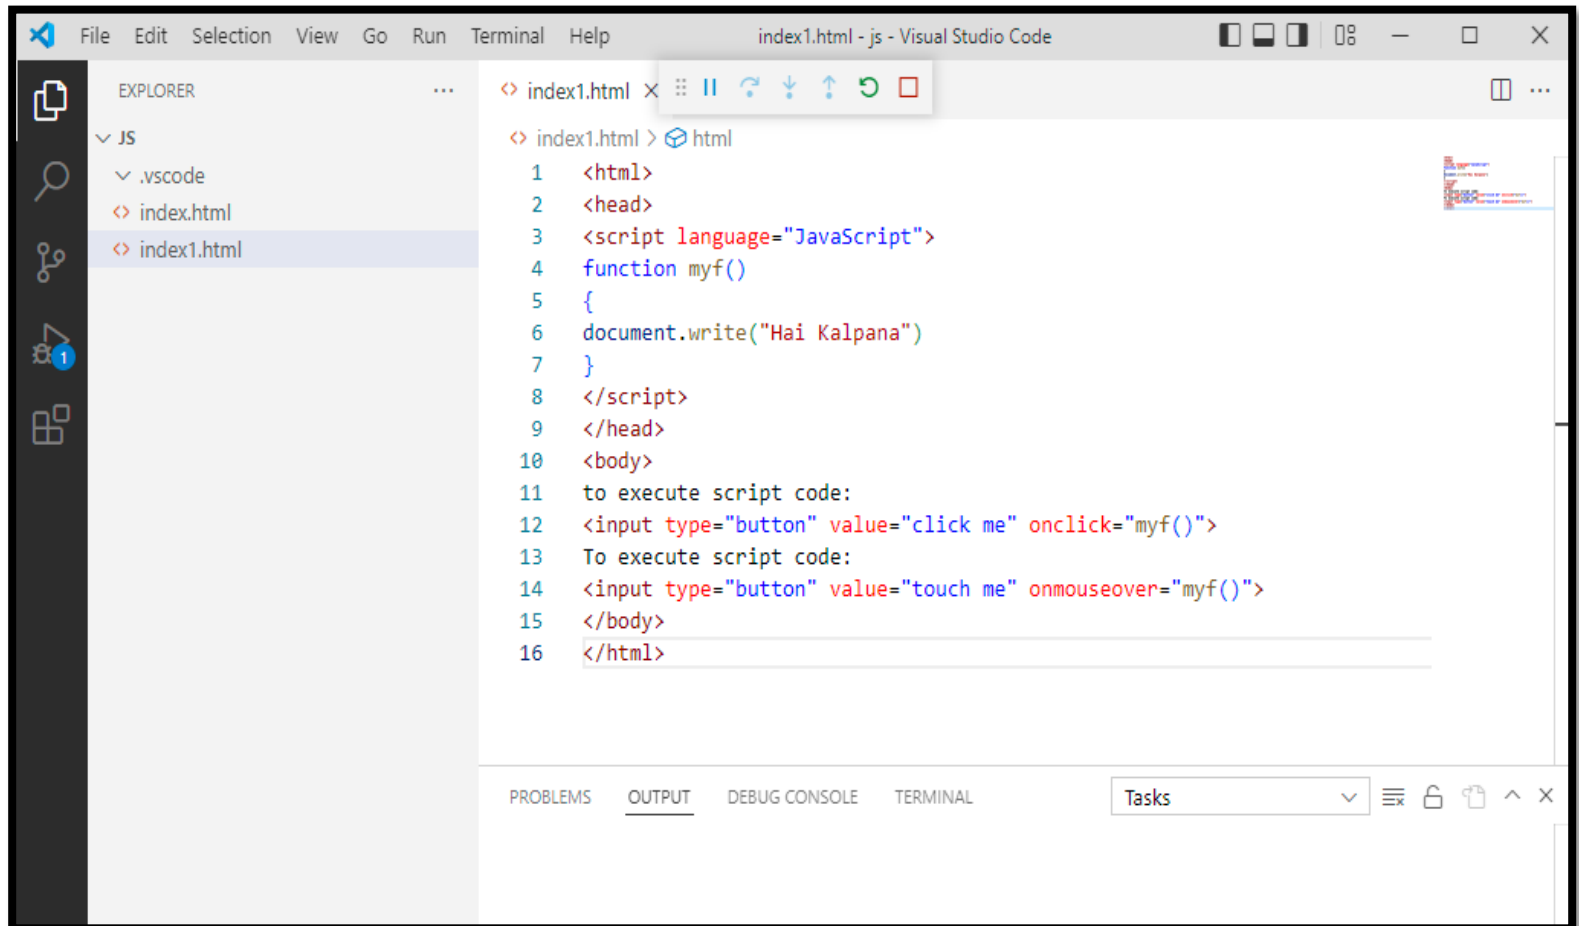

```
<> index.html x
index.html > ...
1 <html>
2 <head>
3 <script language="JavaScript">
4   document.write("hai my name is Kalpana")
5 </script>
6 </head>
7 <br>
8 <body>
9   <script language="JavaScript">
10    document.write("hai my name is Sunil Kumar Reddy")
11  </script></marquee>
12 </body>
13 </html>
14
```

CALL STACK

Open index.html: ind... RUNNING

# Example 2

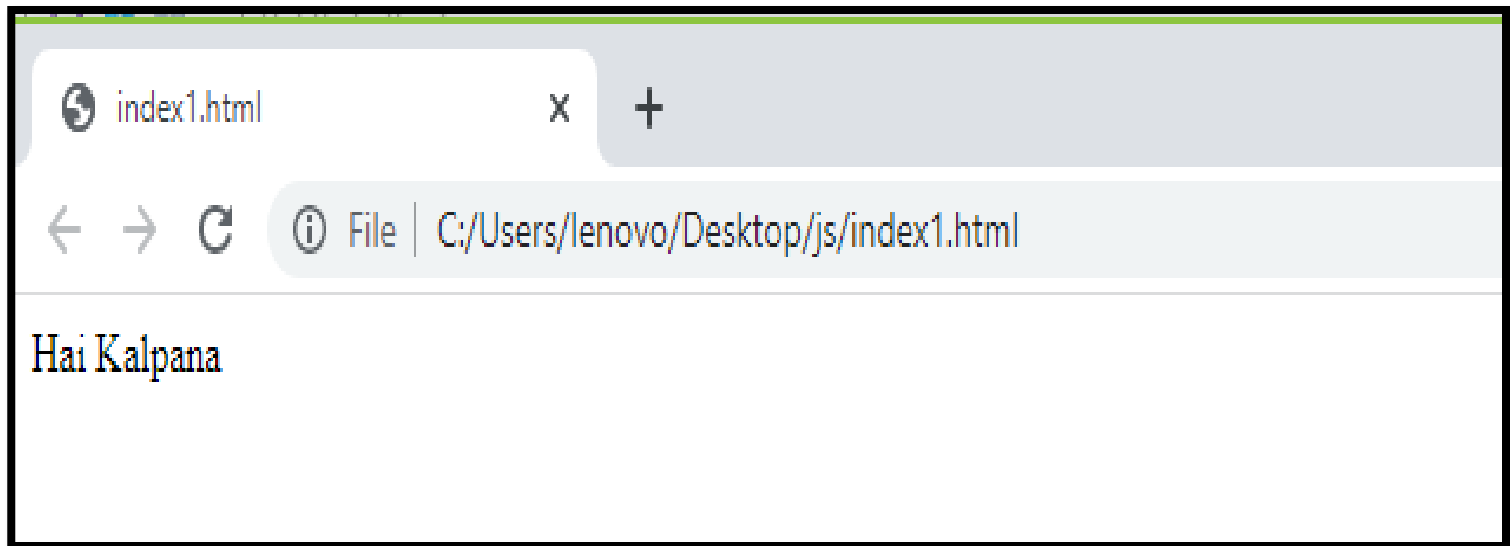

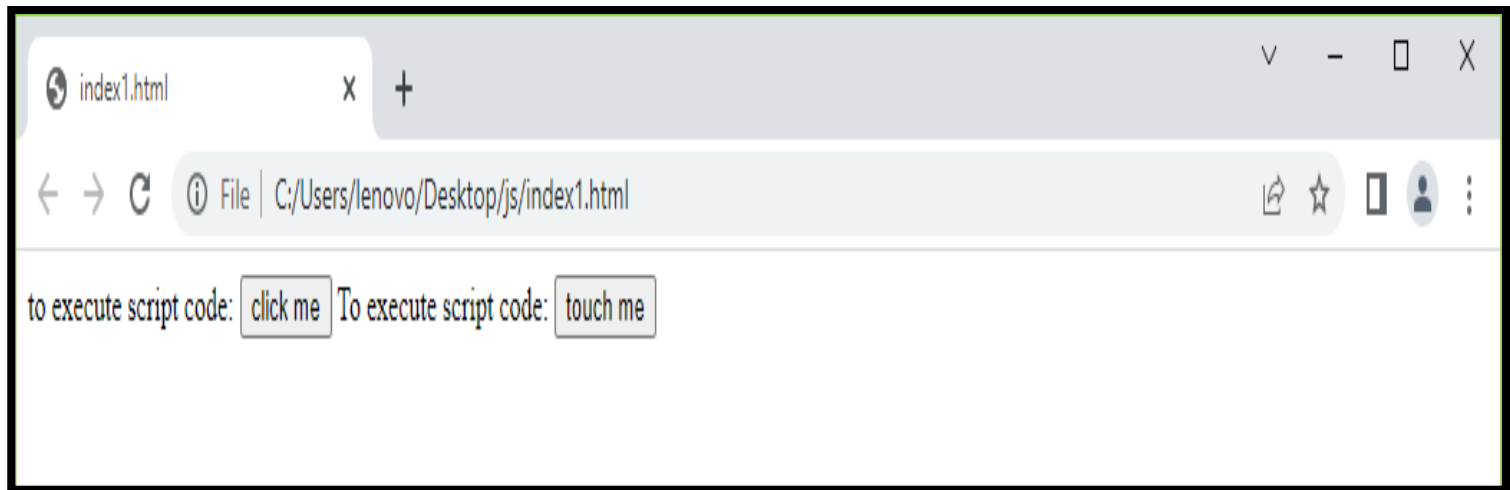

The screenshot shows the Visual Studio Code interface with a file named `index1.html` open. The Explorer sidebar on the left shows the file structure with `index1.html` selected. The main editor area displays the following HTML code:

```
<?xml version="1.0" encoding="UTF-8" ?>
<html>
<head>
<script language="JavaScript">
function myf()
{
document.write("Hai Kalpana")
}
</script>
</head>
<body>
to execute script code:
<input type="button" value="click me" onclick="myf()">
To execute script code:
<input type="button" value="touch me" onmouseover="myf()">
</body>
</html>
```

The bottom status bar shows the 'Tasks' panel is active, with icons for running, saving, and other actions.

# Output

# Java Script syntax rules

## JavaScript syntax rules:

- **JavaScript** is case sensitive language. In this upper case lower case letters are differentiated (not same).

ex:

```
a=20;      A=20;
```

Those the variable name “a” is different from the variable named “A”.

ex:

```
myf( ) // correct
```

```
myF( ) // incorrect
```

; is optional in general JavaScript.

ex:

```
a=20 //valid
```

```
b=30 //valid
```

```
A=10; b=40; // valid
```

However it is required when you put multiple statements in the same line.

# Comment lines & Declaring variables

## Comment lines:

- comments lines are not executable. `//` single line comment  
`/*` this is multi line comment `*/`

## Declaring variable:

- variable is a memory location where data can be stored. In java script variables with any type of data are declared by using the keyword `_var`. All keywords are small letters only.

```
vara;    a=20;  
varstr;  str= "Sunil";  
varc;    c="a";  
vard;    d=30.7;
```

# Example

```
<html>
<body>
<script type="text/javascript">
var firstname;
firstname="Welcome";
document.write(firstname);
document.write("<br />");
firstname="XYZ";
document.write(firstname);
</script>
<p>The script above declares a variable, assigns a value to it, displays the value, change the
value, and displays the value again.</p>
</body>
</html>
```

## Output :

Welcome

XYZ

The script above declares a variable, assigns a value to it, displays the value, change the value, and displays the value again

*The end*
